

Appendix A. summary of estimated population size, parameter estimates, risk of extinction and 90% decline in abundance and needed improvements in lambda to achieve lambda = 1 and to reduce risk of decline or extinction in 50 years to below 5%, assuming that hatchery fish and wild fish reproduce at equal rates. Only estimates for stocks and ESUs that had estimates of the hatchery proportion are shown. Estimates are provided for individual stocks and ESUs (in bold).

¹ Very high extinction risk - probability that extinction in 50 years is over 25%.

ESU	Stock	Population Parameter Estimates						Risk of Extinction			Risk of 90% Decline			Notes ³
		Population Estimate (TS ₀)	μ	σ^2	λ (95% CI)	Prob $\lambda < 1.0$	Prob $\lambda < 0.9$	Req % Inc	50 years (95% CI)	Prob VHER ¹	Req % Inc	50 years (95% CI)	Prob VHRD ²	Req % Inc

² Very high risk of decline - probability that risk of 90% decline in 50 years is over 25%

³ Tests for underlying assumptions were made on the running sums of wild spawner only counts where possible; otherwise total mixed counts were used. The codes designate tests that failed at ($p < .05$). Note that a number of the "fails" are false-fails since the p-value was not adjusted for multiple tests being conducted. If p value is adjusted ($p < .001$) to reduce the probability of a false positive to less than 5%, none of the time series fail the diagnostic tests.

- a. Significant 1st order autocorrelation in $\ln(R_{t+1}/R_t)$ found.
- d. A model with depensatory density-dependence fit the data significantly better than model with no density-dependence. This indicates that the risk estimates are pessimistic.
- t. A model with a trend in μ fit the data significantly better than the model with no trend. This indicates that the risk estimates are optimistic.
- l. The variance versus τ plot showed significant non-linearity ($R^2 < 0.7$) indicating an underestimate of σ^2 .
