Supplemental Table 1. Species names, population locations, dates of observations, and principal pollinators for Dalecham

multilevel comparative analysis presented in Armbruster (1988). Principal pollinators are reported based on the number of hours spent in contact with the flower. Insects were ranked by the number of hours of observation. They are those insects that had the highest pollinator importance ($\text{PI} = \frac{f_a}{f_a + f_s}$, where f_a is the frequency of contact with the anthers, f_s is the frequency of contact with stigma) and the highest visit rate (visits $\cdot \text{inflorescence}^{-1} \cdot \text{hr}^{-1}$). When two species had similar PI scores, both species are reported.
